

Package ‘TukeyRegion’

January 21, 2018

Type Package

Title Tukey Region and Median

Version 0.1.2

Date 2018-01-16

Description

Tukey regions are polytopes in the Euclidean space, viz. upper-level sets of the Tukey depth function on given data. The bordering hyperplanes of a Tukey region are computed as well as its vertices, facets, centroid, and volume. In addition, the Tukey median set, which is the non-empty Tukey region having highest depth level, and its barycenter (= Tukey median) are calculated. Tukey regions are visualized in dimension two and three. For details see Liu, Mosler, and Mozharovskiy (2017) <arXiv:1412.5122>. See file LICENSE.note for additional license information.

TukeyRegion-package *Computation of the Tukey Region and the Tukey Median*

Description

Tukey regions are polytopes in the Euclidean space, *viz.* upper-level sets of the Tukey depth function on given data. The bordering hyperplanes of a Tukey region are computed as well as its vertices, facets, centroid, and volume. In addition, the Tukey median set, which is the non-empty Tukey region having highest depth level, and its barycenter (= Tukey median) are calculated. Tukey regions are visualized in dimension two and three. For details see Liu, Mosler, and Mozharovskyi (2017).

Details

Proposed initially by John W. Tukey in 1975 (see also Donoho and Gasko, 1992) Tukey depth measures centrality of an arbitrary point in the Euclidean space w.r.t. a data cloud. For a point, Tukey (also halfspace or location) depth is defined as the smallest portion of observations that can be cut off by a closed halfspace containing this. For a given depth level Tukey (trimmed) region is defined as the upper level set of the Tukey depth function; it constitutes a closed polytope. The Tukey region of the highest level is referred to as the Tukey median set, while its barycenter is mentioned as the Tukey median. Due to properties of affine invariance, quasiconcavity, vanishing at infinity, high breakdown point of the median set, the Tukey depth attracted attention of statisticians and experienced substantial theoretical development. It is used in numerous applications including multivariate data analysis, outlier detection, tests for location (also scale and symmetry), classification, statistical quality control, imputation of missing data, etc.

Package `TukeyRegion` provides routines for computation (`TukeyRegion`) and visualization (`plot`) of the Tukey depth trimmed region, the Tukey median set and Tukey median (`TukeyMedian`), and Tukey depth weighted and/or trimmed mean (`depth.wm`).

For computation of Tukey depth see function `depth.halfspace` of package `ddalpha`.

depth.wm

Computation of the Tukey depth weighted and/or trimmed mean

Description

Computes the Tukey depth weighted and/or trimmed for a given depth level or for a given number of deepest points.

Usage

```

depth.wm(data, depth.level = 1/nrow(data), weighted = TRUE,
         break.ties = "atRandom", ...)

```

Arguments

data	data set for which the weighted mean should be computed, a matrix having > 2 columns and more rows than columns.
depth.level	either Tukey depth level for trimming (a numeric between 1/(number of rows in data) and 1) or the number of deepest points to take into account (an integer between one and the number of rows in data).
weighted	whether the trimmed mean should be weighted by depth, logical, TRUE by default.
break.ties	the way to break ties if the number of deepest points is given, character. If "atRandom" (by default) ties are broken at random, for any other value input points' order is used.
...	further arguments passed to function depth.halfspace of package ddalpha . See 'Details' for additional information.

Details

After having computed the Tukey depth of each point in data the function operates in two possible modes. If `depth.level` lies between 0 and 1 then the function computes trimmed (weighted if specified by flag `weighted`) mean of all points having at least given depth level. If `depth.level` specifies the number of points (an integer between 1 and number of rows in data) then the trimmed (weighted) mean of `depth.level` deepest points are calculated breaking ties due to argument

break.ties (ties can occur due to discrete nature of the Tukey depth). This follows the idea of Donoho and Gasko (1992), also see this article for the breakdown point.

Depth of points is calculated by means of external function `depth.halfspace` from package `ddalpha`, whose arguments can be specified as well. In particular, argument `exact` specifies whether Tukey depth is computed exactly (TRUE) or approximated (FALSE) by random projections; for the latter case argument `num.directions` specifies the number of random directions to use. For further details about the algorithm see Dyckerhoff and Mozharovskiy (2016).

Value

The function returns the weighted and/or trimmed mean, a point in the d-variate Euclidean space (d is the number of columns in data), a numeric vector.

(Tm\$barycenter)

plot.TukeyRegion *Plot the Tukey Region*

Description

Plots the two-dimensional and the three-dimensional Tukey region.

Usage

```
## S3 method for class 'TukeyRegion'
plot(x, newPlot = TRUE, drawPoints = TRUE,
     drawRidges = TRUE, colorBackground = "white",
     colorPoints = "red", colorFacets = "blue",
     colorRidges = "green", lwd = 1, lty = 1, alpha = 1, ...)
```

Arguments

x	object of class TukeyRegion to be plotted.
newPlot	whether to create a new plot(2D)/scene(3D).
drawPoints	whether to show the data points.
drawRidges	whether to show the ridges; works for non-triangulated facets only.
colorBackground	background color of the plot(2D)/scene(3D).
colorPoints	color of the points in case they are shown.
colorFacets	color of the facets.
colorRidges	color of the facets' ridges in case they are shown.
lwd	line width of the facets in 2D.
lty	line type of the facets in 2D.
alpha	transparency of the facets (and ridges if shown).
...	included for compatibility and should not be used.

Details

If dimension is equal to two, the traditional `plot` is produced. If dimension is equal to three, the 3D-scene is produced using the package `rgl`.

 TukeyMedian

Computation of the Tukey median set and Tukey median

Description

Computes the Tukey median set and its barycenter, the Tukey median.

Usage

```
TukeyMedian(data, algMedian = "bsbarydepth", method = "bfs",
  trgFacets = TRUE, retHalfspaces = FALSE, retHalfspacesNR = FALSE,
  retInnerPoint = FALSE, retVertices = TRUE, retFacets = TRUE,
  retVolume = FALSE, retBarycenter = TRUE, verbosity = 0)
```

Arguments

data	data set for which the Tukey median shall be computed, a matrix having > 2 columns and more rows than columns.
algMedian	the algorithm used to compute the Tukey median, a string containing <code>bsbarydepth</code> , or <code>cutintwo</code> , or <code>downwards</code> , or <code>upwards</code> , see ‘Details’, <code>bsbarydepth</code> by default.
method	the method to use to compute the Tukey region, a string containing <code>bfs</code> , or <code>cmb</code> , or <code>bf</code> , see TukeyRegion , <code>bfs</code> by default.
trgFacets	whether to triangulate facets, logical, FALSE by default. In this case no facet ridges are plotted, see ‘Value’.
retHalfspaces	whether to return all found halfspaces, logical, FALSE by default.
retHalfspacesNR	whether to return non-redundant halfspaces, logical, FALSE by default.
retInnerPoint	whether to return inner point, logical, FALSE by default.
retVertices	whether to return vertices, logical, TRUE by default.
retFacets	whether to return facets, logical, TRUE by default.
retVolume	whether to return volume, logical, FALSE by default.
retBarycenter	whether to return the region’s barycenter, logical, FALSE by default.
verbosity	level of details to print during execution, integer, from 0 (= print nothing) to 2 (= print all details).

Details

The function computes the Tukey median set, *i.e.* the region with the highest depth value, for n points in the Euclidean d -variate space contained in `data`.

It also computes this set’s barycenter, which is the Tukey median. Four search algorithms are implemented: Algorithm `bsbarydepth` is the most efficient, it is the bisection algorithm starting with the lower bound as the maximum of the theoretical minimum and the depth of the componentwise

median, and updating lower bound with the depth of the barycenter of the last found region. Algorithm "cutintwo" sequentially cuts the range of remaining depths into two parts starting with the range from 1 to the upper bound obtained by Liu, Luo, and Zuo (2016). Algorithm "downwards" is checking each depth value decrementally with step 1 starting with the upper bound obtained by Liu, Luo, and Zuo (2016) until the first existing region is found. Algorithm "upwards" is checking each depth value incrementally until the first non-existing region is found.

The main goal of the function is to provide the polytope (Tukey median set) and its barycenter (Tukey median); the settings can be adjusted though. After the median depth is found, the [TukeyRegion](#) function is called.

See function [TukeyRegion](#) for details regarding the output.

Value

The function returns an object of class `TukeyRegion` with fields specified by `ret...-flags` in the arguments:

<code>data</code>	the input data set.
<code>depth</code>	chosen depth level.
<code>halfspacesFound</code>	whether at least one of the determining Tukey region halfspaces has been found.
<code>halfspaces</code>	if requested, halfspaces defining the Tukey region by their intersection, a matrix with number of columns equal to space dimension and where each row corresponds to a halfspace defined by three point numbers in <code>data</code> .
<code>innerPointFound</code>	a logical indicating whether an inner point of the region has been found. If <code>FALSE</code> then the region of the given depth does not exist. If the field is absent then the inner point has not been requested by the input arguments.
<code>innerPoint</code>	coordinates of a point inside of the Tukey region. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
<code>halfspacesNR</code>	non-redundant halfspaces (<i>i.e.</i> those containing Tukey region's facets), a matrix with number of columns equal to space dimension and where each row corresponds to a halfspace defined by three point numbers in <code>data</code> . If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
<code>vertices</code>	vertices of the Tukey region, a matrix with number of columns equal to space dimension and where each row represents vertex coordinates. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments. If field <code>facets</code> is returned, this field is returned as well.
<code>triangulated</code>	a logical repeating the <code>trgFacets</code> input argument. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
<code>facets</code>	facets of the Tukey region. If input argument <code>trgFacets</code> is set, then this is a list where each element is an array enumerating numbers of the rows in field <code>vertices</code> , their number for each facet can vary. If input argument <code>trgFacets</code> is

	unset, then this is a matrix with each row corresponding to a triangulated facet, and no facets' ridges reconstruction is performed, so it cannot be visualized. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
volume	volume of the Tukey region. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
barycenter	the barycenter of the Tukey region. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.

TukeyRegion

Computation of the Tukey Region

Description

Computes the Tukey depth trimmed region for a given depth level.

Usage

```
TukeyRegion(data, depth, method = "bfs",
  trgFacets = FALSE, checkInnerPoint = TRUE,
  retHalfspaces = TRUE, retHalfspacesNR = FALSE,
  retInnerPoint = FALSE, retVertices = FALSE,
  retFacets = FALSE, retVolume = FALSE, retBarycenter = FALSE,
  halfspaces = matrix(0), innerPoint = numeric(1),
  verbosity = 0L)
```

Arguments

data	data set for which the Tukey region shall be computed, a matrix having > 2 columns and more rows than columns.
depth	depth of the Tukey region, an integer between 1 and the half of the number of rows in data.
method	the method to use to compute the Tukey region, a string containing "bfs", or "cmb", or "bf", see 'Details', "bfs" by default.
trgFacets	whether to triangulate facets, logical, FALSE by default. In this case no facet ridges are plotted, see 'Value'.
checkInnerPoint	whether to check correctness of the inner point in case it is provided, logical, TRUE by default.
retHalfspaces	whether to return all found halfspaces, logical, TRUE by default.
retHalfspacesNR	whether to return non-redundant halfspaces, logical, FALSE by default.
retInnerPoint	whether to return inner point, logical, FALSE by default.
retVertices	whether to return vertices, logical, FALSE by default.
retFacets	whether to return facets, logical, FALSE by default.
retVolume	whether to return volume, logical, FALSE by default.
retBarycenter	whether to return the region's barycenter, logical, FALSE by default.
halfspaces	halfspaces defining the Tukey region by their intersection, a matrix with number of columns equal to space dimension and where each row corresponds to a halfspace defined by three point numbers in data.
innerPoint	inner point, a vector of length equal to dimension.
verbosity	level of details to print during execution, integer, from 0 (= print nothing) to 2 (= print all details).

Details

The function computes the Tukey region (upper-level set of the Tukey depth function) for n points in the Euclidean d -variate space contained in `data` at the depth value `depth`.

Three methods are implemented: Method "bfs" is the most efficient, it starts with an initial set of ridges and traverses all facets using the **breadth-first search** algorithm. Method "cmb" considers all subspaces spanned by **combinations** of $d - 1$ points, projects data onto their orthogonal

complements (planes), and searches for bivariate quantiles these planes. Method "bf" employs the **brute-force** strategy by checking all halfspaces defined by hyperplanes containing d points from data. If $d = 2$, method "bf" is used. See Liu, Mosler, and Mozharovskyi (2017) for details on algorithms.

The function proceeds in three main steps. Step 1: Calculate all the halfspaces defining Tukey region in their intersection. Many of them are usually redundant. Step 2: Find the inner point of the Tukey region, *i.e.* a point which lies simultaneously in all the before calculated halfspaces. If such a point does not exist neither does the Tukey region exist for this depth level. The algorithm stops and returns FALSE in the field `innerPointFound`. If the inner point has been found, the algorithm proceeds to Step 3: Filter the halfspaces leaving only those containing the facets of the Tukey region. Step 3 provides information to compute vertices, facets, volume, and barycenter of the Tukey region.

`halfspaces` and/or `innerPoint` can be provided as function arguments.

The function tries to fulfill all the requirements indicated by the input flags. Step 1 is performed anyway (even if `retHalfspaces` is unset, which means the halfspaces just should not be output, except they are provided by the argument `halfspaces`). If any further `ret...`-flag is set Step 2 is performed, except `retHalfspacesNR` is unset and the argument `innerPoint` provided. If any of `retVertices`, `retFacets`, `retVolume`, `retBarycenter` is set, Step 3 is performed.

The region can be visualized in 2- and 3-dimensional space by `plot(...)`, general information can be printed by `print(...)`, statistics can be summarized by `summary(...)`.

Value

The function returns an object of class `TukeyRegion` with fields specified by `ret...`-flags in the arguments:

<code>data</code>	the input data set.
<code>depth</code>	chosen depth level.
<code>halfspacesFound</code>	whether at least one of the determining Tukey region halfspaces has been found.
<code>halfspaces</code>	if requested, halfspaces defining the Tukey region by their intersection, a matrix with number of columns equal to space dimension and where each row corresponds to a halfspace defined by three point numbers in data.
<code>innerPointFound</code>	a logical indicating whether an inner point of the region has been found. If FALSE then the region of the given depth does not exist. If the field is absent then the inner point has not been requested by the input arguments.
<code>innerPoint</code>	coordinates of a point inside of the Tukey region. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
<code>halfspacesNR</code>	non-redundant halfspaces (<i>i.e.</i> those containing Tukey region's facets), a matrix with number of columns equal to space dimension and where each row corresponds to a halfspace defined by three point numbers in data. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.

vertices	vertices of the Tukey region, a matrix with number of columns equal to space dimension and where each row represents vertex coordinates. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments. If field facets is returned, this field is returned as well.
triangulated	a logical repeating the trgFacets input argument. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
facets	facets of the Tukey region. If input argument trgFacets is set, then this is a list where each element is an array enumerating numbers of the rows in field vertices; their number for each facet can vary. If input argument trgFacets is unset, then this is a matrix with each row corresponding to a triangulated facet, and no facets' ridges reconstruction is performed. So it cannot be visualized. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
volume	volume of the Tukey region. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
barycenter	the barycenter of the Tukey region. If the field is absent then either no halfspaces or no inner point have been found or facet computation has not been requested by the input arguments.
