

# Package ‘optimr’

August 17, 2016

**Version** 2016-8.16

**Date** 2016-08-16

**Title** A Replacement and Extension of the 'optim' Function

**Author** John C Nash [aut, cre], Ravi Varadhan [aut], Gabor Grothendieck [ctb]

**Maintainer** John C Nash <nashjc@uottawa.ca>

**Description** Provides a test of replacement and extension of the optim() function to unify and streamline optimization capabilities in R for smooth, possibly box constrained functions of several or many parameters. This version has a reduced set of methods and is intended to be on CRAN.

**License** GPL-2

**LazyLoad** Yes

**Imports** optextras, numDeriv, setRNG, Rvmmin, Rcgmin

**NeedsCompilation** no

**Suggests** knitr, rmarkdown

**VignetteBuilder** knitr

**Repository** CRAN

**Date/Publication** 2016-08-17 00:31:27

---

`coef.opm`*Summarize opm object*

---

### Description

Summarize an "opm" object.

### Usage

```
## S3 method for class 'opm'  
coef(object, ...)  
## S3 replacement method for class 'opm'  
coef(x) <- value
```

### Arguments

<code>object</code>	Object returned by <code>opm</code> .
<code>...</code>	Further arguments to be passed to the function. Currently not used.
<code>x</code>	An <code>opm</code> object.
<code>value</code>	Set parameters equal to this value.

### Value

`coef.opm` returns the best parameters found by each method that returned such parameters. The returned coefficients are in the form of a matrix with the rows named by the relevant methods and the columns named according to parameter names provided by the user in the vector of starting values, or else by "p1", "p2", ..., if names are not provided.

### Examples

```
ans <- opm(fn = function(x) sum(x*x), par = 1:2, method="ALL", control=list(trace=1))  
coef(ans)  
  
## Not run:  
proj <- function(x) x/sum(x)  
f <- function(x) -prod(proj(x))  
ans <- opm(1:2, f)  
ans  
coef(ans) <- apply(coef(ans), 1, proj)  
ans  
  
## End(Not run)
```

## Details

Functions `fn` must return a numeric value.

The control argument is a list.

**maxfeval** A limit on the number of function evaluations used in the search.

**trace** Set 0 (default) for no output, >0 for trace output (larger values imply more output).

**eps** Tolerance used to calculate numerical gradients. Default is 1.0E-7. See source code for `hjn` for details of application.

`dowarn = TRUE` if we want warnings generated by `optimx`. Default is `TRUE`.

`tol` Tolerance used in testing the size of the pattern search step.

## Value

A list with components:

<code>par</code>	The best set of parameters found.
<code>value</code>	The value of the objective at the best set of parameters found.
<code>counts</code>	A two-element integer vector giving the number of calls to <code>'fn'</code> and <code>'gr'</code> respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to <code>'fn'</code> to compute a finite-difference approximation to the gradient.
<code>convergence</code>	An integer code. <code>'0'</code> indicates successful convergence. <code>'1'</code> indicates that the function evaluation count <code>'maxfeval'</code> was reached.
<code>message</code>	A character string giving any additional information returned by the optimizer, or <code>'NULL'</code> .

```

**Description**

Multiple initial parameter wrapper function that calls other R tools for optimization, including the existing `optimr()` function.

**Usage**

```
multistart(parmat, fn, gr=NULL, lower=-Inf, upper=Inf,
           method=NULL, hessian=FALSE,
           control=list(),
           ...)
```

**Arguments**

<code>parmat</code>	a matrix of which each row is a set of initial values for the parameters for which optimal values are to be found. Names on the elements of this vector are preserved and used in the results data frame.
<code>fn</code>	A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
<code>gr</code>	A function to return (as a vector) the gradient for those methods that can use this information. If <code>'gr'</code> is NULL, a finite-difference approximation will be used. An open question concerns whether the SAME approximation code used for all methods, or whether there are differences that could/should be examined?
<code>lower, upper</code>	Bounds on the variables for methods such as "L-BFGS-B" that can handle box (or bounds) constraints.
<code>method</code>	A list of the methods to be used. Note that this is an important change from <code>optim()</code> that allows just one method to be specified. See 'Details'. The default of NULL causes an appropriate set of methods to be supplied depending on the presence or absence of bounds on the parameters. The default unconstrained set is <code>Rvmminu</code> , <code>Rcgminu</code> , <code>lbfgsb3</code> , <code>newuoa</code> and <code>nmkb</code> . The default bounds constrained set is <code>Rvmminb</code> , <code>Rcgminb</code> , <code>lbfgsb3</code> , <code>bobyqa</code> and <code>nmkb</code> .
<code>hessian</code>	A logical control that if TRUE forces the computation of an approximation to the Hessian at the final set of parameters. If FALSE (default), the hessian is calculated if needed to provide the KKT optimality tests (see <code>kkt</code> in 'Details' for the control list). This setting is provided primarily for compatibility with <code>optim()</code> .
<code>control</code>	A list of control parameters. See 'Details'.
<code>...</code>	For <code>optimx</code> further arguments to be passed to <code>fn</code> and <code>gr</code> ; otherwise, further arguments are not used.

**Details**

Note that arguments after `...` must be matched exactly.

See `optimr()` for other details.

**Value**

An array with one row per set of starting parameters. Each row contains:

par	The best set of parameters found.
value	The value of 'fn' corresponding to 'par'.
counts	A two-element integer vector giving the number of calls to 'fn' and 'gr' respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to 'fn' to compute a finite-difference approximation to the gradient.
convergence	An integer code. '0' indicates successful completion
message	A character string giving any additional information returned by the optimizer, or 'NULL'.
hessian	Always NULL for this routine.

**Source**

See the manual pages for `optim()` and the packages the DESCRIPTION suggests.

**Examples**

```
fnR <- function (x, gs=100.0)
{
  n <- length(x)
  x1 <- x[2:n]
  x2 <- x[1:(n - 1)]
  sum(gs * (x1 - x2^2)^2 + (1 - x2)^2)
}
grR <- function (x, gs=100.0)
{
  n <- length(x)
  g <- rep(NA, n)
  g[1] <- 2 * (x[1] - 1) + 4*gs * x[1] * (x[1]^2 - x[2])
  if (n > 2) {
    ii <- 2:(n - 1)
    g[ii] <- 2 * (x[ii] - 1) + 4 * gs * x[ii] * (x[ii]^2 - x[ii +
      1]) + 2 * gs * (x[ii] - x[ii - 1]^2)
  }
  g[n] <- 2 * gs * (x[n] - x[n - 1]^2)
  g
}

pm <- rbind(rep(1,4), rep(pi, 4), rep(-2,4), rep(0,4), rep(20,4))
pm <- as.matrix(pm)
cat("multistart matrix:\n")
print(pm)

ans <- multistart(pm, fnR, grR, method="Rvmin", control=list(trace=0))
ans
```

**Description**

General-purpose optimization wrapper function that calls other R tools for optimization, including the existing `optim()` function. `optimx` also tries to unify the calling sequence to allow a number of tools to use the same front-end. These include `spg` from the `BB` package, `ucminf`, `nlm`, `nlminb`, `Rtnmin`, `lbfgsb3`, `lbfgs`, `nmkb` and `hjkb` from the `dfoptim` package, `uobyqa`, `newuoa` and `bobyqa` from the `minqa` package.

Note that `optim()` itself allows Nelder–Mead, quasi-Newton and conjugate-gradient algorithms as well as box-constrained optimization via L-BFGS-B. Because SANN does not return a meaningful convergence code (`conv`), `opm()` does not call the SANN method, but it can be invoked in `optimr()`.

There is a pseudo-method "ALL" that runs all methods but SANN. Note that this is upper-case.

**Usage**

```
opm(par, fn, gr=NULL, hess=NULL, lower=-Inf, upper=Inf,
    method=c("Nelder-Mead", "BFGS"), hessian=FALSE,
    control=list(),
    ...)
```

**Arguments**

<code>par</code>	a vector of initial values for the parameters for which optimal values are to be found. Names on the elements of this vector are preserved and used in the results data frame.
<code>fn</code>	A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
<code>gr</code>	A function to return (as a vector) the gradient for those methods that can use this information. If <code>'gr'</code> is <code>NULL</code> , a finite-difference approximation will be used. An open question concerns whether the SAME approximation code used for all methods, or whether there are differences that could/should be examined?
<code>hess</code>	A function to return (as a symmetric matrix) the Hessian of the objective function for those methods that can use this information.
<code>lower</code> , <code>upper</code>	Bounds on the variables for methods such as "L-BFGS-B" that can handle box (or bounds) constraints.
<code>method</code>	A vector of the methods to be used, each as a character string. Note that this is an important change from <code>optim()</code> that allows just one method to be specified. See 'Details'. If <code>method</code> has just one element, "ALL" (capitalized), all available and appropriate methods will be tried.

<code>hessian</code>	A logical control that if TRUE forces the computation of an approximation to the Hessian at the final set of parameters. If FALSE (default), the hessian is calculated if needed to provide the KKT optimality tests (see <code>kkt</code> in ‘Details’ for the <code>control</code> list). This setting is provided primarily for compatibility with <code>optim()</code> .
<code>control</code>	A list of control parameters. See ‘Details’.
<code>...</code>	For <code>optimx</code> further arguments to be passed to <code>fn</code> and <code>gr</code> ; otherwise, further arguments are not used.

### Details

This routine is essentially the same as that in package `optimrx` which is NOT in CRAN. This version permits the selection of fewer optimizers in the `method` argument. This reduced selection is intended to avoid failures if dependencies are not available. The available methods are listed in the variable `allmeth` in the file `ctrldefault.R`.

Note that arguments after `...` must be matched exactly.

See the manual for function `optimr()`.

### Value

If there are `npar` parameters, then the result is a dataframe having one row for each method for which results are reported, using the method as the row name, with columns

`par_1`, ..., `par_npar`, `value`, `fevals`, `gevals`, `niter`, `convcode`, `kkt1`, `kkt2`, `xtimes` where

**par\_1 ..**

**par\_npar** The best set of parameters found.

**value** The value of `fn` corresponding to `par`.

**fevals** The number of calls to `fn`.

**gevals** The number of calls to `gr`. This excludes those calls needed to compute the Hessian, if requested, and any calls to `fn` to compute a finite-difference approximation to the gradient.

**niter** For those methods where it is reported, the number of “iterations”. See the documentation or code for particular methods for the meaning of such counts.

**convcode** An integer code. 0 indicates successful convergence. Various methods may or may not return sufficient information to allow all the codes to be specified. An incomplete list of codes includes

1 indicates that the iteration limit `maxit` had been reached.

20 indicates that the initial set of parameters is inadmissible, that is, that the function cannot be computed or returns an infinite, NULL, or NA value.

21 indicates that an intermediate set of parameters is inadmissible.

10 indicates degeneracy of the Nelder–Mead simplex.

51 indicates a warning from the “L-BFGS-B” method; see component message for further details.

52 indicates an error from the “L-BFGS-B” method; see component message for further details.

**kkt1** A logical value returned TRUE if the solution reported has a “small” gradient.

**kkt2** A logical value returned TRUE if the solution reported appears to have a positive-definite Hessian.

**xtimes** The reported execution time of the calculations for the particular method.

The attribute "details" to the returned answer object contains information, if computed, on the gradient (ngatend) and Hessian matrix (nhatend) at the supposed optimum, along with the eigenvalues of the Hessian (hev), as well as the message, if any, returned by the computation for each method, which is included for each row of the details. If the returned object from `optimx()` is `ans`, this is accessed via the construct `attr(ans, "details")`

This object is a matrix based on a list so that if `ans` is the output of `optimx` then `attr(ans, "details")[1, ]` gives the first row and `attr(ans,"details")["Nelder-Mead", ]` gives the Nelder-Mead row. There is one row for each method that has been successful or that has been forcibly saved by `save.failures=TRUE`.

There are also attributes

**maximize** to indicate we have been maximizing the objective

**npar** to provide the number of parameters, thereby facilitating easy extraction of the parameters from the results data frame

**follow.on** to indicate that the results have been computed sequentially, using the order provided by the user, with the best parameters from one method used to start the next. There is an example (`ans9`) in the script `ox.R` in the demo directory of the package.

## Note

Most methods in `optimx` will work with one-dimensional pars, but such use is NOT recommended. Use `optimize` or other one-dimensional methods instead.

There are a series of demos available. Once the package is loaded (via `require(optimx)` or `library(optimx)`), you may see available demos via

```
demo(package="optimx")
```

The demo 'brown\_test' may be run with the command `demo(brown_test, package="optimx")`

The package source contains several functions that are not exported in the NAMESPACE. These are

`optimx.setup()` which establishes the controls for a given run;

`optimx.check()` which performs bounds and gradient checks on the supplied parameters and functions;

`optimx.run()` which actually performs the optimization and post-solution computations;

`scalechk()` which actually carries out a check on the relative scaling of the input parameters.

Knowledgeable users may take advantage of these functions if they are carrying out production calculations where the setup and checks could be run once.

```

---

 optchk

*General-purpose optimization*

---

## Description

A wrapper function that attempts to check the objective function, and optionally the gradient and hessian functions, supplied by the user for optimization. It also tries to check the scale of the parameters and bounds to see if they are reasonable.

## Usage

```
optchk(par, fn, gr=NULL, hess=NULL, lower=-Inf, upper=Inf,
  control=list(), ...)
```

## Arguments

**par** a vector of initial values for the parameters for which optimal values are to be found. Names on the elements of this vector are preserved and used in the results data frame.

fn	A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
gr	A function to return (as a vector) the gradient for those methods that can use this information.
hess	A function to return (as a symmetric matrix) the Hessian of the objective function for those methods that can use this information.
lower, upper	Bounds on the variables for methods such as "L-BFGS-B" that can handle box (or bounds) constraints.
control	A list of control parameters. See 'Details'.
...	For <code>optimx</code> further arguments to be passed to <code>fn</code> and <code>gr</code> ; otherwise, further arguments are not used.

### Details

Note that arguments after ... must be matched exactly.

While it can be envisaged that a user would have an analytic hessian but not an analytic gradient, we do NOT permit the user to test the hessian in this situation.

Any names given to `par` will be copied to the vectors passed to `fn` and `gr`. Note that no other attributes of `par` are copied over. (We have not verified this as at 2009-07-29.)

### Value

A list of the following items:

**grOK** TRUE if the analytic gradient and a numerical approximation via `numDeriv` agree within the `control$grtesttol` as per the R code in function `grchk`. NULL if no analytic gradient function is provided.

**hessOK** TRUE if the analytic hessian and a numerical approximation via `numDeriv::jacobian` agree within the `control$hesstesttol` as per the R code in function `hesschk`. NULL if no analytic hessian or no analytic gradient is provided. Note that since an analytic gradient must be available for this test, we use the Jacobian of the gradient to compute the Hessian to avoid one level of differencing, though the `hesschk` function can work without the gradient.

**scalebad** TRUE if the larger of the `scaleratios` exceeds `control$scaletol`

**scaleratios** A vector of the parameter and bounds scale ratios. See the function code of `scalechk` for the computation of these values.

### References

See the manual pages for `optim()` and the packages the DESCRIPTION suggests.

## Examples

```
fr <- function(x) { ## Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) { ## Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
    200 * (x2 - x1 * x1))
}

myctrl<- ctrldefault(2)
myctrl$trace <- 3
mychk <- optchk(par=c(-1.2,1), fr, grr, lower=rep(-10,2), upper=rep(10,2), control=myctrl)
cat("result of optchk\n")
print(mychk)
```

---

optimr

*General-purpose optimization*

---

## Description

General-purpose optimization wrapper function that calls other R tools for optimization, including the existing `optim()` function. `optimr` also tries to unify the calling sequence to allow a number of tools to use the same front-end. These include `spg` from the `BB` package, `ucminf`, `nlm`, and `nlmminb`. Note that `optim()` itself allows Nelder–Mead, quasi-Newton and conjugate-gradient algorithms as well as box-constrained optimization via L-BFGS-B. Because SANN does not return a meaningful convergence code (`conv`), `optimz::optim()` does not call the SANN method.

## Usage

```
optimr(par, fn, gr=NULL, lower=-Inf, upper=Inf,
       method=NULL, hessian=FALSE,
       control=list(),
       ...)
```

## Arguments

<code>par</code>	a vector of initial values for the parameters for which optimal values are to be found. Names on the elements of this vector are preserved and used in the results data frame.
<code>fn</code>	A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.

gr	A function to return (as a vector) the gradient for those methods that can use this information. If 'gr' is NULL, a finite-difference approximation will be used. An open question concerns whether the SAME approximation code used for all methods, or whether there are differences that could/should be examined?
lower, upper	Bounds on the variables for methods such as "L-BFGS-B" that can handle box (or bounds) constraints.
method	A list of the methods to be used. Note that this is an important change from optim() that allows just one method to be specified. See 'Details'. The default of NULL causes an appropriate set of methods to be supplied depending on the presence or absence of bounds on the parameters. The default unconstrained set is Rvmminu, Rcgminu, lbfgsb3, newuoa and nmkb. The default bounds constrained set is Rvmminb, Rcgminb, lbfgsb3, bobyqa and nmkb.
hessian	A logical control that if TRUE forces the computation of an approximation to the Hessian at the final set of parameters. If FALSE (default), the hessian is calculated if needed to provide the KKT optimality tests (see kkt in 'Details' for the control list). This setting is provided primarily for compatibility with optim().
control	A list of control parameters. See 'Details'.
...	For optimx further arguments to be passed to fn and gr; otherwise, further arguments are not used.

## Details

Note that arguments after ... must be matched exactly.

This routine is essentially the same as that in package optimrx which is NOT in CRAN. This version permits the selection of fewer optimizers in the method argument. This reduced selection is intended to avoid failures if dependencies are not available. The available methods are listed in the variable allmeth in the file ctrldefault.R.

By default this function performs minimization, but it will maximize if control\$maximize is TRUE. The original optim() function allows control\$fnscale to be set negative to accomplish this. DO NOT use both methods.

Possible method codes are 'Nelder-Mead', 'BFGS', 'CG', 'L-BFGS-B', 'nlm', 'nlnminb', 'Rcgmin', 'Rvmmin' and 'hjn'. These are in base R or in CRAN repositories or part of this package.

The default methods for unconstrained problems (no lower or upper specified) are an implementation of the Nelder and Mead (1965) and a Variable Metric method based on the ideas of Fletcher (1970) as modified by him in conversation with Nash (1979). Nelder-Mead uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions. The Variable Metric method, "BFGS" updates an approximation to the inverse Hessian using the BFGS update formulas, along with an acceptable point line search strategy. This method appears to work best with analytic gradients. ("Rvmmin" provides a box-constrained version of this algorithm.

If no method is given, and there are bounds constraints provided, the method is set to "L-BFGS-B".

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak-Ribiere or Beale-Sorenson updates). The particular implementation is now dated, and improved yet simpler codes have been implemented. Furthermore, "Rcgmin" allows

box constraints as well as fixed (masked) parameters. Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in optimization problems with a large number of parameters.

Method "L-BFGS-B" is that of Byrd *et al.* (1995) which allows *box constraints*, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method is selected by the original `optim()` function, with a warning. Unfortunately, the authors of the original Fortran version of this method released a correction for bugs in 2011, but these have not been incorporated into the distributed R codes, which are a C translation of a version that appears to be from the mid-1990s. Conversations with Jorge Nocedal suggest that the bug should NOT affect L-BFGS-B. However, CRAN does have a direct translation of the 2001 Fortran in package `lbfgsb3`.

Nocedal and Wright (1999) is a comprehensive reference for such methods.

Function `fn` can return NA or Inf if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of `fn`. However, some methods, of which "L-BFGS-B" is known to be a case, require that the values returned should always be finite.

While `optim` can be used recursively, and for a single parameter as well as many, this may not be true for `optimr`. `optim` also accepts a zero-length `par`, and just evaluates the function with that argument, but such an input is not recommended.

Method "nlm" is from the package of the same name that implements ideas of Dennis and Schnabel (1983) and Schnabel *et al.* (1985). See `nlm()` for more details.

Method "nlnmb" is the package of the same name that uses the minimization tools of the PORT library. The PORT documentation is at <URL: <http://netlib.bell-labs.com/cm/cs/ctr/153.pdf>>. See `nlnmb()` for details. (Though there is very little information about the methods.)

Method "Rcgmin" is from the package of that name. It implements a conjugate gradient algorithm with the Dai and Yuan update (2001) and also allows bounds constraints on the parameters. (Rcgmin also allows mask constraints – fixing individual parameters – but there is as yet no interface from "optimr".)

Method "Rvmmmin" is from the package of that name. It implements the same variable metric method as the base `optim()` function with method "BFGS" but allows bounds constraints on the parameters. (Rvmmmin also allows mask constraints – fixing individual parameters – but there is as yet no interface from "optimr".)

Method "hjn" is a conservative implementation of a Hooke and Jeeves (1961)

The control argument is a list that can supply any of the following components:

`trace` Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. `trace = 0` gives no output (To understand exactly what these do see the source code: higher levels give more detail.)

`follow.on` = TRUE or FALSE. If TRUE, and there are multiple methods, then the last set of parameters from one method is used as the starting set for the next.

`save.failures` = TRUE if we wish to keep "answers" from runs where the method does not return `convcode==0`. FALSE otherwise (default).

`maximize = TRUE` if we want to maximize rather than minimize a function. (Default FALSE). Methods `nlm`, `nlminb`, `ucminf` cannot maximize a function, so the user must explicitly minimize and carry out the adjustment externally. However, there is a check to avoid usage of these codes when `maximize` is TRUE. See `fnscale` below for the method used in `optim` that we deprecate.

`all.methods = TRUE` if we want to use all available (and suitable) methods.

`kkt = FALSE` if we do NOT want to test the Kuhn, Karush, Tucker optimality conditions. The default is TRUE. However, because the Hessian computation may be very slow, we set `kkt` to be FALSE if there are more than 50 parameters when the gradient function `gr` is not provided, and more than 500 parameters when such a function is specified. We return logical values `KKT1` and `KKT2` TRUE if first and second order conditions are satisfied approximately. Note, however, that the tests are sensitive to scaling, and users may need to perform additional verification. If `kkt` is FALSE but `hessian` is TRUE, then `KKT1` is generated, but `KKT2` is not.

`all.methods = TRUE` if we want to use all available (and suitable) methods.

`kkttol = value` to use to check for small gradient and negative Hessian eigenvalues. Default = `.Machine$double.eps^(1/3)`

`kkt2tol = Tolerance` for eigenvalue ratio in KKT test of positive definite Hessian. Default same as for `kkttol`

`starttests = TRUE` if we want to run tests of the function and parameters: feasibility relative to bounds, analytic vs numerical gradient, scaling tests, before we try optimization methods. Default is TRUE.

`dowarn = TRUE` if we want warnings generated by `optimx`. Default is TRUE.

`badval = The value` to set for the function value when `try(fn())` fails. Default is `(0.5)*.Machine$double.xmax`

`useNumDeriv = TRUE` if the `numDeriv` function `grad()` is to be used to compute gradients when the argument `gr` is NULL or not supplied.

The following control elements apply only to some of the methods. The list may be incomplete. See individual packages for details.

`fnscale` An overall scaling to be applied to the value of `fn` and `gr` during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on `fn(par)/fnscale`. For methods from the set in `optim()`. Note potential conflicts with the control `maximize`.

`parscale` A vector of scaling values for the parameters. Optimization is performed on `par/parscale` and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. For `optim`.

`ndeps` A vector of step sizes for the finite-difference approximation to the gradient, on `par/parscale` scale. Defaults to `1e-3`. For `optim`.

`maxit` The maximum number of iterations. Defaults to `100` for the derivative-based methods, and `500` for "Nelder-Mead".

`abstol` The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.

`reltol` Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of `reltol * (abs(val) + reltol)` at a step. Defaults to `sqrt(.Machine$double.eps)`, typically about `1e-8`. For `optim`.

alpha, beta, gamma Scaling parameters for the "Nelder-Mead" method. alpha is the reflection factor (default 1.0), beta the contraction factor (0.5) and gamma the expansion factor (2.0).

REPORT The frequency of reports for the "BFGS" and "L-BFGS-B" methods if control\$trace is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B".

type for the conjugate-gradients method. Takes value 1 for the Fletcher-Reeves update, 2 for Polak-Ribiere and 3 for Beale-Sorenson.

lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method, It defaults to 5.

factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is 1e7, that is a tolerance of about 1e-8.

pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

Any names given to par will be copied to the vectors passed to fn and gr. Note that no other attributes of par are copied over. (We have not verified this as at 2009-07-29.)

### Value

For 'optim', a list with components:

par	The best set of parameters found.
value	The value of 'fn' corresponding to 'par'.
counts	A two-element integer vector giving the number of calls to 'fn' and 'gr' respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to 'fn' to compute a finite-difference approximation to the gradient.
convergence	An integer code. '0' indicates successful completion
message	A character string giving any additional information returned by the optimizer, or 'NULL'.
hessian	Always NULL for this routine.

---

polyopt

*General-purpose optimization - multiple starts*

---

**Description**

Multiple initial parameter wrapper function that calls other R tools for optimization, including the existing `optimr()` function.

**Usage**

```
polyopt(par, fn, gr=NULL, lower=-Inf, upper=Inf,
        methcontrol=NULL, hessian=FALSE,
        control=list(),
        ...)
```

**Arguments**

<code>par</code>	a vector of initial values for the parameters for which optimal values are to be found. Names on the elements of this vector are preserved and used in the results data frame.
<code>fn</code>	A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
<code>gr</code>	A function to return (as a vector) the gradient for those methods that can use this information. If 'gr' is NULL, a finite-difference approximation will be used. An open question concerns whether the SAME approximation code used for all methods, or whether there are differences that could/should be examined?
<code>lower, upper</code>	Bounds on the variables for methods such as "L-BFGS-B" that can handle box (or bounds) constraints.
<code>methcontrol</code>	An data frame of which each row gives an optimization method, a maximum number of iterations and a maximum number of function evaluations allowed for that method. Each method will be executed in turn until either the maximum iterations or function evaluations are completed, whichever is first. The next method is then executed starting with the best parameters found so far, else the function exits.
<code>hessian</code>	A logical control that if TRUE forces the computation of an approximation to the Hessian at the final set of parameters. If FALSE (default), the hessian is calculated if needed to provide the KKT optimality tests (see <code>kkt</code> in 'Details' for the <code>control</code> list). This setting is provided primarily for compatibility with <code>optim()</code> .
<code>control</code>	A list of control parameters. See 'Details'.
<code>...</code>	For <code>optimx</code> further arguments to be passed to <code>fn</code> and <code>gr</code> ; otherwise, further arguments are not used.

**Details**

Note that arguments after ... must be matched exactly.

See `optimr()` for other details.

**Value**

An array with one row per method. Each row contains:

<code>par</code>	The best set of parameters found for the method in question.
<code>value</code>	The value of 'fn' corresponding to 'par'.
<code>counts</code>	A two-element integer vector giving the number of calls to 'fn' and 'gr' respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to 'fn' to compute a finite-difference approximation to the gradient.
<code>convergence</code>	An integer code. '0' indicates successful completion
<code>message</code>	A character string giving any additional information returned by the optimizer, or 'NULL'.
<code>hessian</code>	Always NULL for this routine.

**Source**

See the manual pages for `optim()` and the packages the DESCRIPTION suggests.

**Examples**

```
fnR <- function (x, gs=100.0)
{
  n <- length(x)
  x1 <- x[2:n]
  x2 <- x[1:(n - 1)]
  sum(gs * (x1 - x2^2)^2 + (1 - x2)^2)
}
grR <- function (x, gs=100.0)
{
  n <- length(x)
  g <- rep(NA, n)
  g[1] <- 2 * (x[1] - 1) + 4*gs * x[1] * (x[1]^2 - x[2])
  if (n > 2) {
    ii <- 2:(n - 1)
    g[ii] <- 2 * (x[ii] - 1) + 4 * gs * x[ii] * (x[ii]^2 - x[ii +
      1]) + 2 * gs * (x[ii] - x[ii - 1]^2)
  }
  g[n] <- 2 * gs * (x[n] - x[n - 1]^2)
  g
}

x0 <- rep(pi, 4)
mc <- data.frame(method=c("Nelder-Mead", "Rvmmin"), maxit=c(1000, 100), maxfeval= c(1000, 1000))

ans <- polyopt(x0, fnR, grR, methcontrol=mc, control=list(trace=0))
```

```
ans
mc <- data.frame(method=c("Nelder-Mead", "Rvmmin"), maxit=c(100, 100), maxfeval= c(100, 1000))

ans <- polyopt(x0, fnR, grR, methcontrol=mc, control=list(trace=0))
ans

mc <- data.frame(method=c("Nelder-Mead", "Rvmmin"), maxit=c(10, 100), maxfeval= c(10, 1000))

ans <- polyopt(x0, fnR, grR, methcontrol=mc, control=list(trace=0))
ans
```
